

MAIL SERVER

Project Report

CHANDER SHEKHAR

Enrollment No.: 1713104040

Under the Supervision of
Dr. P.RAJAKUMAR

**School of Computing Science and Engineering
Greater Noida, Uttar Pradesh
Winter 2019-2020**

ABSTRACT

An abstract of Mail Server using Web Design measuring performance and modification to the web site.

This report is conducted in order to set the foundations upon which the final project. The title of the project is: MAIL SERVER and is supervised by Dr. P.RAJAKUMAR. The main target of this report is to conduct a thorough and in-depth analysis of the vast field of Software development and at the same time explore the opportunities and the conditions that could lead into building a successful website. The simplicity and ease of access of a design are the main things that facilitate mail server project. This paper presents a performance study of the ISP (Internet Service Provider) mail servers. By using the SPECmail2001 benchmark to test a commercial mail service— M Daemon 5.0.1, we explore the both network and I/O performance of mail servers with user populations between 200 to 10,000. File system traces are also collected for analysis. From the benchmark results, trace-driven simulations and offline trace analysis, we arrive at several important conclusions for the ISP mail servers and give the technical suggestions correspondingly. We observed that, in SMTP and POP sessions, the initial network connection setup usually takes the very long time. I/O latencies contribute up to 40–55% of the data transfer time of e-mail requests, especially when the user population is high. We also found that mail servers have better file system temporal and spatial locality than web servers. Most files are short-lived. Because of the skewed files access patterns, a reasonably-sized file system cache can capture most file accessed.

Introduction

Mailing services gives free web based electronic mail. Mailing Services enables you to acquire new customers and to increase growth opportunities with existing customers. With a wide range of Direct Mail Lists Services, label mailing or mail merge services, we enable you to communicate with customers in a better way.

Aim-: The main aim of our project is to provide a mailing services which lets you compose mail and send to a respective selected object. You can send documents or images (attachments).Also one can search emails with the search technology within the inbox, outbox , drafts.

Objective-: To prepare new mailing system on PHP which provide all the services provide by any general mailing services with some extra features such as easy to operate ,free messaging services are objective to make this project at very huge level but we just learn how to make mailing service system we are able in future to work over this project easily and provide much better facilities. So here we are showing you dummy project on mailing services prepared with help of PHP and some other designing tools.

Vision-: Our vision for this project and training is to build and maintains a customer-oriented culture. The customer satisfaction is what we aspire for. Hence we are to provide a mailing service that is easy and comfortable to control and function with certain additional facilities.

PROJECT SCOPE

Mailing server is also a very secure system. It provides you security as your profile is protected with a password.

You can change the password when you feel insecure with the old password. There is also the password recovery system in case you forgot your password you can recover your profile by verifying your alternate email or phone number.

- Compose an email.
- Send an email
- Receive an email
- Showing the detail of the received mail
- Saving the email ids in a contact list
- Saving an email in the form of draft
- Secured by password
- Recovery of the password

GOALS

- To prepare new mailing system on PHP which provide all the services provided by any general mailing services with some extra features such as easy to operate ,free messaging services are objective to make this project at very huge level but we just learn how to make mailing service system we are able in future to work over this project easily and provide much better facilities. So here we are showing you dummy project on mailing services prepared with help of PHP and some other designing tools. Our vision for this project and training is to build and maintains a customer-oriented culture. The customer satisfaction is what we aspire for. Hence we are to provide a mailing service that is easy and comfortable to control and function with certain additional facilities.

Requirement Analysis

Hardware requirements

Number	Description
1	PC with 20 GB Hard disk
2	PC with 256 MB RAM
3	PC with Pentium 1 and Above

Software requirements

Number	Description	Type
1	Operating System	Windows XP/Windows
2	Language	PHP
3	Server side Script	PHP script
4	Client side Script	Java script,Html
5	Server	WAMP 5.0
6	Database	MySQL
7	IDE	Text pad
8	Designing Tools	XARA,Fireworks,Dreamweaver,Paintbrush
9	Browser	Internet Explorer/Mozilla etc.

OVERALL DESCRIPTION

A mail server (or email server) is a computer system that sends and receives email. In many cases, web servers and mail servers are combined in a single machine. However, large ISPs and public email services (such as Gmail and Hotmail) may use dedicated hardware for sending and receiving email.

In order for a computer system to function as a mail server, it must include mail server software. This software allows the system administrator to create and manage email accounts for any domains hosted on the server. For example, if the server hosts the domain name "techterms.com," it can provide email accounts ending in "@techterms.com."

Mail servers send and receive email using standard email protocols. For example, the SMTP protocol sends messages and handles outgoing mail requests. The IMAP and POP3 protocols receive messages and are used to process incoming mail. When you log on to a mail server using a webmail interface or email client, these protocols handle all the connections behind the scenes.

Mail server software is available for multiple platforms. The most popular mail server for Windows is Microsoft Exchange Server, an enterprise product used by large businesses. However, many other options exist, including Ipswitch IMail Server, IceWarp Mail Server, MailEnable, and hMailServer.

Key features:

The many different features of mail server include:

- automatic reply to messages
- auto-forward and redirection of messages
- facility to send copies of a message to many people
- automatic filing and retrieval of messages
- addresses can be stored in an address book and retrieved instantly
- notification if a message cannot be delivered
- emails are automatically date and time stamped
- signatures can be attached
- files, graphics or sound can be sent as attachments, often in compressed formats
- webmail and mobile email can be used to receive and send messages while on the move

SYSTEM FEATURES

PHP

PHP: Hypertext Preprocessor, is a widely used, general-purpose scripting language that was originally designed for web development, to produce dynamic web pages. It can be embedded into HTML and generally runs on a web server, which needs to be configured to process PHP code and create web page content from it. It can be deployed on most web servers and on almost every operating system and platform free of charge.

PHP was originally created by Rasmus Lerdorf in 1995 and has been in continuous development ever since. The main implementation of PHP is now produced by The PHP Group and serves as the de facto standard for PHP as there is no formal specification. PHP is free software released under the PHP License, which is incompatible with the GNU General Public License (GPL) because of restrictions on the use of the term PHP

PHP has evolved to include a command line interface capability and can also be used in standalone graphical applications.

USAGE

PHP is a general-purpose scripting language that is especially suited for web development. PHP generally runs on a web server. Any PHP code in a requested file is executed by the PHP runtime, usually to create dynamic web page content. It can also be used for command-line scripting and client-side GUI applications. PHP can be deployed on most web servers, many operating systems and platforms, and can be used with many relational database management systems. It is available free of charge, and the PHP Group provides the complete source code for users to build, customize and extend for their own use.

PHP primarily acts as a filter, taking input from a file or stream containing text and/or PHP instructions and outputs another stream of data; most commonly the output will be HTML. Since PHP 4, the PHP parser compiles input to produce byte code for processing by the Zend Engine, giving improved performance over its interpreter predecessor

Originally designed to create dynamic web pages, PHP now focuses mainly on server-side scripting, and it is similar to other server-side scripting languages that provide dynamic content from a web server to a client, such as Microsoft's Active Server Pages, Sun Microsystems' JavaServer Pages and mod_perl. PHP has also attracted the development of many frameworks that provide building blocks and a design structure to promote rapid application development (RAD). Some of these include CakePHP, Symfony,

CodeIgniter, and Zend Framework, offering features similar to other web application frameworks.

About HTML

HTML, which stands for **Hyper Text Markup Language**, is the predominant markup language for web pages. It provides a means to create structured documents by denoting structural semantics for text such as headings, paragraphs, lists etc as well as for links, quotes, and other items. It allows images and objects to be embedded and can be used to create interactive forms. It is written in the form of HTML elements consisting of "tags" surrounded by angle brackets within the web page content. It can include or can load scripts in languages such as JavaScript which affect the behavior of HTML processors like Web browsers; and Cascading Style Sheets (CSS) to define the appearance and layout of text and other material. The W3C, maintainer of both HTML and CSS standards, encourages the use of CSS over explicit presentational markup.

Hyper Text Markup Language(HTML) is the encoding scheme used to create and format a web document. A user need not be an expert programmer to make use of HTML for creating hypertext documents that can be put on the internet.

Most graphical e-mail clients allow the use of a subset of HTML (often ill-defined) to provide formatting and semantic markup not available with plain text. This may include typographic information like coloured headings, emphasized and quoted text, inline images and diagrams. Many such clients include both a GUI editor for composing HTML e-mail messages and a rendering engine for displaying them. Use of HTML in e-mail is controversial because of compatibility issues, because it can help disguise phishing attacks, because it can confuse spam filters and because the message size is larger than plain text.

NAMING CONVENTIONS

The most common filename extension for files containing HTML is .html. A common abbreviation of this is .htm, which originated because some early operating systems and file systems, such as DOS and FAT, limited file extensions to three letters.

HTML APPLICATION

An HTML Application is a Microsoft Windows application that uses HTML and Dynamic HTML in a browser to provide the application's graphical interface. A regular HTML file is confined to the security model of the web browser, communicating only to web servers and manipulating only webpage objects and site cookies. An HTA runs as a fully trusted application and therefore has more privileges, like creation/editing/removal of files and Windows Registry entries. Because they operate outside the browser's security model, HTAs cannot be executed via HTTP, but must be downloaded (just like an EXE file) and executed from local file system

ABOUT JAVASCRIPT

JavaScript is an object-oriented scripting language used to enable programmatic access to objects within

both the client application and other applications. It is primarily used in the form of client-side JavaScript, implemented as an integrated component of the web browser, allowing the development of enhanced user interfaces and dynamic websites. JavaScript is a dialect of the ECMAScript standard and is characterized as a dynamic, weakly typed, prototype-based language with first-class functions. JavaScript was influenced by many languages and was designed to look like Java, but to be easier for non-programmers to work with.

PROTOTYPE-BASED

JavaScript uses prototypes instead of classes for inheritance. It is possible to simulate many class-based features with prototypes in JavaScript.

Functions double as object constructors along with their typical role. Prefixing a function call with new creates a new object and calls that function with its local this keyword bound to that object for that invocation. The constructor's prototype property determines the object used for the new object's internal prototype. JavaScript's built-in constructors, such as Array, also have prototypes that can be modified.

Unlike many object-oriented languages, there is no distinction between a function definition and a method definition. Rather, the distinction occurs during function calling; a function can be called as a method. When a function is called as a method of an object, the function's local this keyword is bound to that object for that invocation.

USAGE

The primary use of JavaScript is to write functions that are embedded in or included from HTML pages and interact with the Document Object Model (DOM) of the page.

Because JavaScript code can run locally in a user's browser (rather than on a remote server) it can respond to user actions quickly, making an application feel more responsive. Furthermore, JavaScript code can detect user actions which HTML alone cannot, such as individual keystrokes. Applications such as Gmail take advantage of this: much of the user-interface logic is written in JavaScript, and JavaScript dispatches requests for information (such as the content of an e-mail message) to the server. The wider trend of Ajax programming similarly exploits this strength.

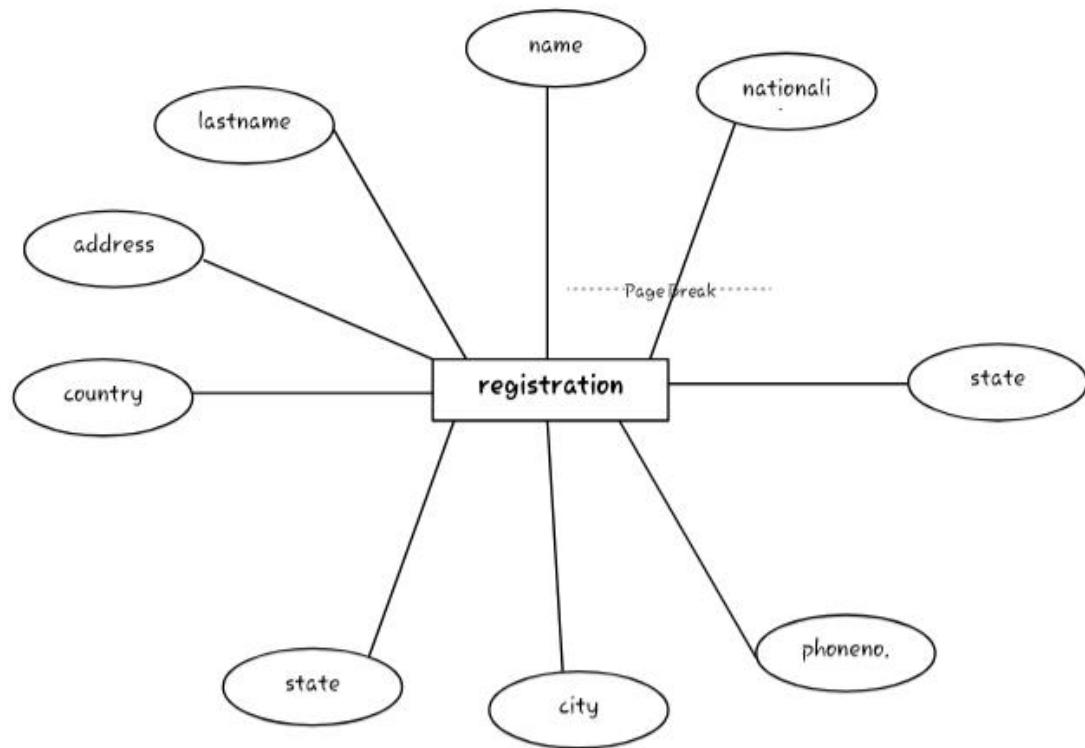

A JavaScript engine (also known as *JavaScript interpreter* or *JavaScript implementation*) is an interpreter that interprets JavaScript source code and executes the script accordingly. The first JavaScript engine was created by Brendan Eich at Netscape Communications Corporation, for the Netscape Navigator web browser. A web browser is by far the most common host environment for JavaScript. Web browsers typically use the public API to create "host objects" responsible for reflecting the DOM into JavaScript.

About us

<h2 style="background:#99FF33;padding:5px" align="left">About us</h2>

<p>About Phptpoint.Com

Phptpoint?s free PHP Online Tutorial has heaps of PHP Interview question **and** well-run Interview question with answer associated to core php, cake php, codeigniter, mysql, joomla etc. which can assist you to crack the Interview **for** PHP developer.</p>

<p>Here, at phptpoint we begin from the scratch where we can lead you on the practice of these languages. This is a free **and** online site where the students who wants to build a career in the same profession, can be trained about the working of the PHP. Perhaps you can go to any of the institutes where you have to spend a hefty amount also **and** apart from that you need to give time **as** well. But here at Phptpoint we provide functional **and** easy to understand PHP tutorials **for** beginners with examples. This is an advantage of the PHP tutorial **for** PHP interested students **as** well **as** the experts of PHP programming who can learn many more things through our site. </p>

<p>

There is always distrust in the wits of the beginners that a site can?t help them in developing a better mode of understanding. But your search **for** a good tutorial ends up at Phptpoint. We have made this site **for** the benefit of the people who approach us in the zest of learning, so we have developed it in a way which can sort out the queries hand to hand. The visitors visiting to Phptpoint can directly ask **for** a solution to their queries. Once we know your trouble point, our job begins to find an apt way out **for** you.

</p>

<p>

Apart from free online tutorial Phptpoint provides you free downloading facility also. Students can easily download free php projects. There are huge numbers of projects available **for** your reference. You can select them to see **as** an example **and** start learning through those live examples, because examples are the best ways **for** describing a particular thing. You can pick any topic from the online php tutorial **and** we will guide you with a complete package from the definition to the explanation in a well versed manner.

</p>

Change pass

```
<?php
include('connectivity.php');

Conclusion-

The methods of distributing mail between multiple servers presented here, represents a scalable solution for applications where hosting mail for a domain on a single server becomes impractical. The cost of this method is, typically mail delivery and retrieval must travel though one extra hop adding to latency and effectively doubling network utilisation for mail. The former is a problem inherent in any multi-step mechanism and the latter can be alleviated by running multiple physical interfaces on a machine and spreading traffic between the interfaces.

At this stage, the solution is somewhat incohesive and some work needs to be done, drawing the different aspects of this solution together. In particular, pulling together the pop map, aliases or the user_map and general rules, into a single resource would simplify management greatly. Migration is another area that requires significant work and a scalable way for the mail servers to communicate with each other needs to be developed. It would be advantageous, if the mail servers could constantly be updated each other on their current load and users, so that migrations could occur as bottle-necks manifested.

The architecture developed has placed emphasis on a single user's mail only ever being located on a single server. This alleviates contention between servers for locks and avoids having to query each server for knowledge of a mailbox, as all servers have access to information on where an mailbox is housed. It is of particular note that intelligent construction of pop maps and aliases or user_map entries could be designed to migrate users' mailboxes to one of the servers closest to the user. When used in conjunction with routing techniques, to force traffic for a particular port onto a specific host, the user could be forced to always access one of the closest servers. Hence, a mail system distributed amongst separate physical locations can easily be created, enhancing the quality of service to end users through faster, more reliable access.

OUTPUT

The screenshot shows a web page with a header featuring a banner image of three men in suits. The banner text reads "FUEL YOUR CAREER WITH JOB ORIENTED PROGRAM & CERTIFICATION" and "Gain a Competitive Edge and Enhance Your Credentials". Below the banner is a navigation bar with links: HOME, ABOUT US, LOGIN, NEW USER?, and CONTACT US. The main content area contains the text "Welcome to My mail server....." and "About My mail server - email from Google this a mail server by using". In the bottom right corner of the content area, there is a link labeled "Latest Updates".

The screenshot shows a web page with a sidebar on the left containing links: COMPOSE, INBOX, SENT, TRASH, and DRAFT. The main content area is titled "Welcome hema". At the top of the content area are five buttons: CHANGE THEME, CHANGE PASSWORD, EDIT YOUR PROFILE, UPDATE LATEST NEWS, and LOGOUT. Below these buttons is a form for file upload. The form has fields for "Title" and "Contents", a file input field labeled "upload your file" with "Choose File No file chosen", and a button group with "RESET" and "UPDATE".
